13. ABSTRACT (Maximum 200 words) <p>In this Phase I SBIR project, supported by the U.S. Air Force through Wright Laboratories, the properties of a promising new class of solvents called fluoriodocarbons (FICs) were investigated. FICs are odorless, colorless, evaporate quickly and cleanly, are nonflammable, and appear to have low toxicity and negligible environmental impact. The properties of FICs and potential blending solvents were tabulated and laboratory tests of thermal stability, cleaning effectiveness, and materials compatibility were conducted on three pure FICs (1-C₃F₇I, 1-C₄F₉I, and 1-C₆F₁₃I). All three FICs have excellent thermal stability, excellent materials compatibility, and high cleaning effectiveness on a variety of difficult soils. FICs are particularly effective at removing perfluorinated greases. Pure FICs undergo less than 0.6% decomposition when exposed to 175°C for four months, and several solid stabilizers were proven effective. Neither air, water, nor moderate amounts of light affect FIC stability. The most attractive FIC solvent appears to be 1-C₄F₉I, because of its physical properties and high cleaning performance. The results have demonstrated the technical feasibility of FIC solvents as "drop-in" replacements for CFC-113, TCA, TCE, and PCE. The proposed Phase II effort, designed to bring to market a new group of validated, approved, and commercially viable nonaqueous solvents, is discussed.</p>

1. Background

A. History of Ozone-Depleting Solvents

The solvents CFC-113 and 1,1,1-trichloroethane (also called TCA or methyl chloroform) have been widely used for many years for cleaning of metals, electronics, and precision surfaces because of their effectiveness, rapid evaporation, nonflammability, and low toxicity. They have been very convenient to use because they do not require water washes or complex equipment. Millions of pounds of these solvents have been used annually by the U. S. Air Force (USAF) for maintenance and repair of mechanical equipment for Air Force systems and ground support. Many other Government and industrial organizations are also major users of these solvents. However, because of concerns about stratospheric ozone depletion and the resulting legislation, the production of these chemicals will be phased out by December 31, 1995 (Refs. 1-6).

Because of the phaseout of these ozone-depleting chemicals, new chemicals and processes are needed for many cleaning operations in both military and civilian applications. Trichloroethylene (TCE) and perchloroethylene (PCE) can be used in some cases, but these chemicals are suspected carcinogens and require elaborate and expensive systems to recover the vapors and avoid exposure of workers. In addition, TCE and PCE are not easily biodegradable and can cause contamination problems if they reach ground water.

In some cases flammable or combustible solvents such as isopropyl alcohol or *d*-limonene can be used, but strict precautions must be taken to avoid ignition sources and these solvents may pose potential volatile organic compound (VOC) problems (contributing to smog formation). Although hydrochlorofluorocarbons (HCFCs) once appeared promising, concerns over their ozone-depletion potentials (ODPs) and toxicity have severely limited their applicability as solvents. Recently, perfluorocarbons and hydrofluorocarbons have been promoted as alternative cleaning solvents, but these substances are poor cleaners and have relatively high global warming potentials (GWPs).

Aqueous cleaning consists of spray or immersion using water plus detergents and alcohols, followed by rinsing with water and drying. In some cases aqueous cleaning can be used, where water can penetrate adequately, does not become trapped, and does not harm the substrate. When aqueous cleaning is possible, it is attractive for the low cost, worker safety, and low environmental impact. However, there are many cleaning situations in manufacturing and repair of military and civilian equipment where water cannot penetrate adequately, would become trapped, or would harm the substrate; for these cases alternative nonaqueous cleaners are needed.

Alternative cleaning processes already in use or under development include blasting technologies (e.g., plastic beads, wheat starch, solid CO₂), supercritical CO₂ cleaning, and plasma cleaning. In the electronics area, several no-clean options are under development, including low-solids flux and fluxless solder. However, all of these alternative technologies require substantial investment, retooling, and retraining, and are not universally applicable.

B. Desired Properties for a Replacement Solvent

An ideal solvent should meet the following requirements:

- have high solvency for the contaminants present
- penetrate well
- represent minimal or no health hazard
- have an ODP and GWP of zero or as close to zero as possible
- not present a volatile organic compound (VOC) problem
- not present a flammability hazard
- have no adverse effects on materials or components, including long-term durability
- be cost effective
- be recyclable
- be biodegradable
- be suitable for use with existing equipment.

These are quite stringent requirements; no solvents in current use meet all of these criteria. If a nonflammable, nontoxic, effective, environmentally safe nonaqueous cleaner can be identified, it will be a virtual drop-in replacement for TCA, CFC-113, TCE, and PCE. Hundreds of millions of dollars of investment in cleaning equipment (such as vapor degreasers) could remain in use, eliminating the economic and environmental costs of scrapping existing equipment, manufacturing new equipment, and retraining personnel.

C. Classes of Alternative Solvents

Solvents fall into three categories: aqueous, semiaqueous, or nonaqueous. Aqueous cleaners use water plus additives such as detergents and alcohols. The advantages of aqueous systems include low toxicity, nonflammability, low environmental impact, and low cost. Potential concerns include adequate penetration, possible residues, and the effects of water on the substrate. Several aerospace firms (including Northrop, Rockwell, Douglas, Rocketdyne, and Aerojet) are implementing aqueous cleaning of parts.

In semi-aqueous processes, the substrate is cleaned with an organic solvent such as *d*-limonene (a terpene), then rinsed with deionized water to remove traces of solvent. Although this process is effective in some applications, potential concerns include the toxicity and flammability of the organic solvent, possible residues from incomplete rinsing, and the complexity of the process.

Nonaqueous cleaners are organic liquids that do not require aqueous rinsing. This category includes TCA, CFC-113, TCE, PCE, alcohols, esters, ethers, hydrocarbons, and ketones. Nonaqueous cleaners possess the substantial advantages of excellent removal of oils and greases, rapid clean evaporation (for sufficiently volatile solvents), and elimination of the need to expose the surface to water. Potential concerns in general include flammability, toxicity, materials compatibility, adequate volatility for removal, and environmental impact. Nonaqueous cleaners in use include isopropyl alcohol (IPA) and TCE, which may require elaborate engineering systems to minimize the flammability and toxicity risks, respectively.

Solvents are needed that penetrate well, remove a variety of soils, and evaporate quickly and cleanly, as well as being nonflammable and nontoxic. No such solvents are now available to replace CFC-113 and TCA.

D. Government and Industry Initiatives in Cleaning Technologies

Several government and industry initiatives are underway to develop improved cleaning technologies. Organizations currently conducting programs to assist in the assessment and evaluation of cleaning technologies include trade organizations, the Environmental Protection Agency (EPA), the Department of Energy (DOE), and the Department of Defense (DoD). An industry cooperative to track and provide up-to-date cleaning technology information, the Industry Cooperative For Ozone Layer Protection (ICOLP), has been established. The EPA and DoD are working together to reevaluate military specifications (MILSPECs) and standards (MILSTDs) to reflect the phaseout of ozone-depleting solvents. The National Laboratories are conducting several programs to assess and develop alternative solvents and cleaning processes, including testing solvents, plasma cleaning, and supercritical carbon dioxide cleaning technologies. Manufacturers worldwide are reassessing their cleaning requirements and implementing "environmentally friendly" alternatives; Northern Telecom, AT&T, Motorola, and IBM are among those who have provided leadership. The cleaning agent, recovery/recycling/reclamation, and industrial drying industries have also begun to develop new technologies.

During the past few years several new cleaning agents and processes have been developed or their applicability has been expanded. These include, for example, the use of aqueous, semi-aqueous, and nonaqueous cleaners, supercritical carbon dioxide, blasting technologies, and plasma cleaning.

There are several reasons why the U.S. Air Force cannot count on any of the current efforts to provide the best possible cleaners for its specific needs. Established manufacturers in all businesses (including solvent cleaning) tend to look for alternatives that are available right now, rather than carrying out the research needed to provide optimal solutions, even though currently available options may require complex procedures and give poor performance. The USAF has unique requirements that may not be addressed by solvent manufacturers. The history of technology shows that major innovations are usually made by creative individuals working outside of major established organizations (Refs. 7 and 8). Small companies with technologically innovative ideas have a difficult time getting new technologies adopted by larger manufacturers. One of the main advantages of the USAF SBIR program is that it nurtures innovative technologies to meet USAF needs.

2. Phase I Effort

A. Properties of Fluoriodocarbons (FICs)

ETEC has identified a new group of nonaqueous solvents that appears to provide "drop-in" replacements for CFC-113, TCA, TCE and PCE in many applications. These alternative chemicals are known as fluoriodocarbons (FICs) and contain carbon, fluorine, and iodine. FICs are nonflammable, do not deplete stratospheric ozone, do not cause global warming, have low

toxicity, have high cleaning effectiveness, and may be usable in existing vapor degreasers. In addition, FICs are simple to use, evaporate quickly and cleanly, and do not require exposure of the parts being cleaned to water. These solvents also appear very attractive for hand wipe and spray applications. If FICs are found to have acceptable thermal stability, they may also be usable in existing vapor degreasers. Both pure FICs and blends with conventional solvents appear attractive. Conventional solvents that may be blended with FICs in any proportions include alcohols, esters, ethers, hydrocarbons, and ketones.

Four FICs, both alone and in blends, show the greatest promise as replacement non-aqueous solvents. Structures, names, and boiling points of these four FICs are shown in Table 1.

Table 1. Fluoroiodocarbons to be used in solvents

Formula	Condensed Formula	Names	Boiling Point (°C)
CF ₃ (CF ₂) ₂ I	1-C ₃ F ₇ I	perfluoro- <i>n</i> -propyl iodide 1-iodoperfluoropropane heptafluoro-1-iodopropane	41
CF ₃ (CF ₂) ₃ I	1-C ₄ F ₉ I	perfluoro- <i>n</i> -butyl iodide 1-iodoperfluorobutane nonafluoro-1-iodobutane	67
CF ₃ (CF ₂) ₄ I	1-C ₅ F ₁₁ I	perfluoro- <i>n</i> -pentyl iodide 1-iodoperfluoropentane undecafluoro-1-iodopentane	94
CF ₃ (CF ₂) ₅ I	1-C ₆ F ₁₃ I	perfluoro- <i>n</i> -hexyl iodide 1-iodoperfluorohexane tridecafluoro-1-iodohexane	117

The properties of these FICs make them the most promising alternative nonaqueous solvents for the future. These chemicals are nonflammable, and in fact are excellent extinguishants, comparable to halons. In published reports of cup-burner testing by two independent laboratories, FICs have shown extinguishing ability for hydrocarbon fires almost identical to that of halons on a gas volume percent basis (Refs. 9-11). FICs also have attractive boiling points, vapor pressures, and other physical properties.

The environmental properties of FICs are very appealing. They have essentially zero ODP because if released at ground level they are destroyed within two days by sunlight and will never reach the stratosphere (Refs. 12 and 13). The C-I bond is very susceptible to photolysis, even at ground level. The short atmospheric lifetime also gives FICs GWPs hundreds to thousands of times lower than chlorofluorocarbons, hydrochlorofluorocarbons, perfluorocarbons, and

hydrofluorocarbons. There is substantial evidence that FICs destroy components of smog, and are in fact "anti-VOCs" (Refs. 14-17).

The limited toxicity data reported on FICs are very encouraging. For example, one study reported that the level of exposure to $\text{CF}_3\text{CF}_2\text{CF}_2\text{I}$ necessary to cause lethality in 50% of a mouse population in 2 hours (mice 2-hr LC_{50}) was 404 g/L, corresponding to 3.1% by gas volume and 250,000 ppm by weight (Ref. 18). This is a relatively high concentration, indicating a fairly safe chemical.

Very little solubility (cleaning ability) data had been reported in the literature on FICs before this Phase I effort. Because of their chemical structures, however, FICs were expected to have similar solubility characteristics to CFCs. They should have much greater solubility than perfluorocarbons for both nonpolar and polar contaminants because of the presence of the large, polarizable iodine atom. In blends, the solubility properties are expected to be determined by both components. For example, a blend of 50% by volume ethyl acetate and 50% perfluorobutyl iodide is expected to have solubility properties of both the FIC and ethyl acetate.

The author (in unfunded work) had carried out some rough preliminary tests of FIC-based solvents and had given a talk on the subject (Ref. 19). In very crude qualitative tests of cleaning effectiveness (visual inspection of contaminated glass slides) the author had found that perfluoro-*n*-butyl iodide ($1\text{-C}_4\text{F}_9\text{I}$) and perfluoro-*n*-hexyl iodide ($1\text{-C}_6\text{F}_{13}\text{I}$) gave good removal of WD40 oil and 10W30 motor oil, fair to good removal of molybdenum spray lubricant and molybdenum grease, and fair removal of lanolin. These results compared favorably with cleaning results of conventional flammable solvents. Thus FICs appeared to be quite effective solvents.

Blends of conventional solvents with FICs can provide the advantages of lower cost and customized solubility performance. FICs can be blended with a wide variety of well-known solvents from the classes of alcohols, esters, ethers, hydrocarbons, and ketones. The FICs tested ($\text{C}_4\text{F}_9\text{I}$ and $\text{C}_6\text{F}_{13}\text{I}$) were found to be miscible in all proportions with all solvents tested, including isopropyl alcohol, ethanol, ethyl acetate, acetone, methyl ethyl ketone, hexanes, toluene, naphtha, and limonene. In general, addition of 20% to 50% of the FIC by volume was found to render blends nonflammable when an open flame was touched to the surface. In some cases, addition of as little as 1% of an FIC rendered a mixture nonflammable (e.g., 1% $\text{C}_4\text{F}_9\text{I}$ in *d*-limonene).

Azeotropic blends are particularly attractive because they do not change composition on evaporation. Thus an azeotropic solvent would not tend to lose the more volatile component if exposed to air. An important part of Phase II of this effort is the laboratory identification of nonflammable azeotropic blends of FICs with conventional solvents.

FICs have very low surface tension, which will aid penetration into tight spaces. This low surface tension is shown by the size of the drops; the smaller the drop, the lower the surface tension. FICs have over 200 drops per mL, whereas water has about 20 drops to the milliliter and most organic solvents have about 60.

At this time, FICs are available only in research quantities and are expensive. In small quantities they now cost about \$1/g, similar to the current cost of HFC-134a in research quantities. HFC-134a sells for \$9/lb in bulk, and it is expected that FICs should be in about that price range when produced in bulk. Chemicals drop in price dramatically (by factors of 30 or

more) as larger quantities are produced and FICs are relatively simple molecules to prepare. In addition, in solvent blends they will be in mixtures with common, inexpensive solvents which typically cost about one or two dollars a pound. Thus all the solvents under investigation here are expected to be available soon for lower costs than CFCs, which are now selling for about \$15/lb in many locations because of taxes and shortages, and are continuing to increase in price. FICs appear to provide the *only* candidate solvents at this time that are nonflammable, have high cleaning abilities, low toxicity, and low environmental impact, and could be manufactured at reasonable cost.

B. Objectives, Scope, and Approach

This Phase I effort involved five tasks: (1) collection of known information on pure components of solvent blends, (2) identification of soils to be removed, (3) quantitative testing of cleaning effectiveness of pure FICs, (4) thermal stability testing of pure FICs, and (5) reporting of results, including recommendations for Phase II testing.

The Phase I effort screened FICs for top-ranking solvent candidates and provided initial laboratory validation of cleaning effectiveness and thermal stability. The three top-ranking pure FIC solvents shown in Table 1 (1-C₃F₇I, 1-C₄F₉I, and 1-C₆F₁₃I) were tested for cleaning abilities and thermal stabilities. In addition, initial materials compatibility tests were conducted and the properties of conventional solvents for blending were collected and assessed. The results of this Phase I effort are a set of top-ranked FIC solvents, with known cleaning abilities and thermal stabilities, to undergo comprehensive validation (both alone and in blends) in Phase II.

It was determined early in the Phase I effort that one of the FICs listed in Table 1, perfluoro-n-pentyl iodide (1-C₅F₁₁I) appears to have attractive physical properties, but cannot be purchased even in laboratory research quantities at this time. A search of Chem Sources On-Line (a comprehensive, up-to-date database of vendors for chemicals) revealed no vendors for this chemical. Two custom synthesis laboratories (Ryan Scientific and Flura Corp.) that synthesize other FICs were requested to prepare quotations for synthesis of one kg of this chemical, but both declined to provide a quotation. The starting material for the synthesis (perfluorohexanoic acid) is sold by at least two chemical producers (3M and Montefluos), so it is believed that the five-carbon FIC could be prepared without any special difficulty. However, because of the lack of availability even for laboratory testing, perfluoro-n-pentyl iodide was judged less attractive as a candidate solvent than the other three FICs listed in Table 1 at this time. For this reason it was not tested as part of this Phase I effort.

The overall objectives of this Phase I effort were to identify, test, and rank the most attractive pure FIC solvents. The specific objectives and scope of this effort, with approaches taken, included:

(1) Collection of known information on the properties of chemicals of interest.

Existing data on the physical and environmental properties, cleaning abilities, materials compatibilities, and thermal stabilities of the 57 chemicals of interest (both FICs and conventional solvents) were collected, organized, and critically assessed. Collections of information such as the CRC Handbook of Chemistry and Physics, the Aldrich Chemical Catalog, and the on-line

databases of Chemical Abstracts Service (CAS) and Beilstein's Handbook of Organic Chemistry were searched (Refs. 20-23).

(2) Identification of the Soils of Interest

Literature searches and interviews with USAF personnel were conducted to determine the soils of greatest interest in aircraft maintenance operations.

(3) Quantitative testing of cleaning effectiveness of pure FICs.

Quantitative laboratory tests were carried out to determine the effectiveness of pure FICs in removing nineteen difficult soils of interest. Protocols were based on those developed at Sandia and Lawrence Livermore National Labs, for example those described in Ref. 24. Tables of data and graphs of soil removal vs. time were prepared.

(4) Thermal stability testing of pure FICs

Three top-ranking pure FICs underwent thermal stability testing. Samples with and without potential stabilizers were sealed in glass tubes and heated in ovens at 90, 120, 150, and 175°C for up to four months. Potential stabilizers tested included both solids and liquids. The solids tested were copper metal, silver metal, activated charcoal, zeolite molecular sieve, and silica filter-drier beads. The liquids tested were combinations of the following additives reported to stabilize chlorinated solvents: methanol, nitromethane, 1,2-butylene oxide, 1,4-dioxane, 1,3-dioxolan, and furan. The sample tubes were removed periodically from the ovens and analyzed by visible spectroscopy to quantify decomposition. The data obtained were analyzed to provide information on rates of decomposition and stabilizing effects of additives.

(5) Ranking of solvents for Phase II testing.

Based on the results of the data collected, the attractiveness of the FIC solvents has been ranked based on a combination of cleaning effectiveness, physical and environmental properties, toxicity, and expected materials compatibility. A set of top-ranking FIC solvents has been recommended for Phase II testing.

To achieve all of these objectives, the following questions were addressed in this Phase I effort:

- (1) What is known about the physical properties, cleaning effectiveness, materials compatibilities, toxicities, and thermal stabilities of the solvent components of interest?
- (2) What soils must be removed from mechanical equipment for Air Force systems and ground support?
- (3) What are the solubility properties (cleaning abilities) of pure FICs?
- (4) How thermally stable are pure FICs, with and without stabilizers?
- (5) Which FIC-containing solvents rank highest for Phase II testing?

Two optional transitional tasks are now underway. These tasks consist of (1) *Calculation of properties of solvent blends* and (2) *Selection of optimal blends*. The optional transition phase will provide a set of top-ranking solvent blends containing FICs for Phase II testing.

3. Properties of FICs and Potential Blending solvents

A. Search Strategy

A literature search was conducted to find and tabulate data of interest on the components considered for use in FIC-containing solvents. Components include the FICs listed in Table 1 and the other components shown in Table 2, which are common solvents with boiling points between 35°C and 200°C (the normal boiling point range of solvents used for a wide variety of applications). Properties of interest included physical properties such as boiling point, vapor pressure as a function of temperature, liquid density, critical temperature and pressure, flash point, and heat of vaporization as well as toxicity, flammability, materials compatibility, thermal stability, and environmental properties. Environmental properties include atmospheric lifetimes, global warming potentials, ozone-depletion potentials, and contributions to tropospheric air pollution (smog).

Sources of information included books, journals, patents, and solvent databases such as the Solvent Handbook Database System (SHDS) at the Idaho National Engineering Lab (INEL) SHDS, the Solvent Alternative Guide of the EPA (SAGE), and OZONET, the database of the International Cooperative for Ozone Layer Protection (ICOLP). On-line literature databases including Chemical Abstracts Service (CAS) and the National Technical Information Service (NTIS) were searched, and personal contacts were interviewed.

B. Results

The results of this search for properties of solvents of interest are shown in Table 3. Most of the properties desired on the solvents of interest were found in the literature.

C. Toxicities of FICs

Apart from thermal stability, one of the most common concerns expressed about FICs regards their toxicities. For this reason a review of toxicity information on FICs was conducted and the results are reported here.

The most thoroughly studied FIC at this time is trifluoromethyl iodide (CF_3I) because of interest by the USAF in this compound as a drop-in replacement for Halon 1301. The author first identified CF_3I and its blends as the top Halon 1301 candidates in a previous effort sponsored by the Air Force (Ref. 9). Armstrong Labs and ManTech have performed extensive testing on CF_3I and reported data include the following: mice 15-minute LC_{50} 27.4% by gas volume (74.9% by mass, mechanism of lethality: anesthesia), no lethality on exposure of mice to 6% by gas volume (30% by mass) for 72 hours, and cardiac sensitization observed in a beagle at 0.4% by gas volume (2.7% by mass) under the test conditions of 1000 times normal adrenalin levels (10 times maximum levels under stress). Several positive Ames tests were observed. For heptafluoro-*n*-propyl iodide ($\text{CF}_3\text{CF}_2\text{CF}_2\text{I}$, 1- $\text{C}_3\text{F}_7\text{I}$), the reported 15-minute rat LC_{50} is 4.9% by gas volume (34.4% by mass). This relatively high LC_{50} indicates a high degree of safety.

Table 2. Solvent components that may be blended with fluoroiodocarbons

Class	Name(s)	Formula
alcohols	1-butanol	$\text{HO}(\text{CH}_2)_3\text{CH}_3$
	2-butanol	$\text{CH}_3\text{CH}(\text{OH})\text{CH}_2\text{CH}_3$
	ethanol	$\text{CH}_3\text{CH}_2\text{OH}$

There is a small amount of previous published data on toxicity of FICs (reviewed in Refs. 9 and 25). For example, one report shows that a dog exposed to 50% by volume (91% by mass) of CF_3I for 30 seconds survived and exhibited no signs of anesthesia (Ref. 26). It was reported that after 30 seconds of exposure the dog experienced coughing, choking, retching, and convulsions. It is very encouraging that no anesthesia or lethality were observed at this high concentration. The coughing, choking, retching, and convulsions could well have been caused by traces of acid gases (HF and HI) or by oxygen deprivation (asphyxiation), since displacement of 50% of the air in the test chamber by CF_3I would leave the oxygen concentration below 11%, a level that cannot sustain mammalian life. In modern test protocols at high concentrations of halocarbons, oxygen is added to keep the total oxygen concentration near the normal level, but there is no indication that oxygen was added in this 1953 test. In the Registry of Toxic Effects of Chemical Substances (RTECS) it is reported that the mice LC_{50} for 2-hour exposure to $\text{CF}_3\text{CF}_2\text{CF}_2\text{I}$ is 404 g/m^3 (Ref. 18). This corresponds to 25% by weight or 3.34% by gas volume. Again this relatively high LC_{50} indicates a high degree of safety.

Several iodocarbons have been used as radiopaque agents in humans, providing improved contrast for X-rays (Ref. 27). In fact radiopaque agents are one of the largest worldwide uses of iodine at this time. The fact that these compounds have been injected or ingested into many humans with no ill effects provides additional evidence for the low toxicity of many iodocarbons.

No data are reported on the long-term effects of exposure to FICs. It would be reasonable to assume that highly volatile compounds such as CF_3I would have little or no long-term health effects because they will leave the body within minutes of exposure. For less volatile compounds, the long-term effects are more difficult to predict. Because the body can excrete or use iodine, it is unlikely that any adverse effects will be observed from the iodine atoms from FICs. In general, the main area of potential concern for most haloalkanes is possible alkylation of important biological molecules. However, because fluorinated 1-iodoalkanes are hundreds or thousands of times less reactive than most alkyl halides in both $\text{S}_{\text{N}}1$ (substitution, nucleophilic, unimolecular) and $\text{S}_{\text{N}}2$ (substitution, nucleophilic, bimolecular) type reactions, very little if any alkylation should occur.

CF_3I has already been approved for use in unoccupied areas under the EPA's Significant New Alternatives Program (SNAP), and has appeared on the published SNAP list of acceptable alternatives. Because this approval applies only to unoccupied areas, cardiac sensitization data was not required for this approval. Thus, regardless of future findings, CF_3I is likely to be an important halon replacement for unoccupied spaces. For unoccupied spaces, no human exposure is expected in use; only workers handling the chemicals are at possible risk of exposure. Because the chemicals are handled in closed systems, only an accident would expose workers. Additional engineering controls can be incorporated to minimize this hazard.

Recent toxicity results give increased importance to blends containing FICs. Blends can be designed to improve performance, lower cost, and decrease toxicity. Often two chemicals used in combination are less toxic than linearly predicted.

None of the toxicity results to date should have significant adverse effects on usage of FICs as solvents. The mouse LC_{50} of 1- $\text{C}_3\text{F}_7\text{I}$ (3.3%/2hr) is more than 8 times higher than that of TCA (0.39%/2 hr), indicating that 1- $\text{C}_3\text{F}_7\text{I}$ is substantially safer than the widely-used TCA. The

LC₅₀ data also indicate that 1-C₃F₇I has similar toxicity to ethanol. If necessary, appropriate engineering controls on solvents (e.g., fume hoods or enclosed systems) can be used to minimize exposure, and blending of FICs with conventional solvents can decrease toxicity as well as cost. The commonly-used refrigerant CFC-11 has a no observable adverse effect limit (NOAEL) and lowest observable adverse effect limit (LOAEL) lower than CF₃I, indicating that CF₃I is safer than CFC-11. No lethality was observed on exposure of mice to 6% CF₃I for 72 hours. Thus CF₃I appears much safer than the widely used beverage and solvent ethanol, which killed half the mice exposed to 2.1% for 4 hours.

Table 4 lists some comparative toxicity data on halogenated hydrocarbons in use as solvents, refrigerants, foam blowing agents, and firefighting agents (Refs. 18 and 25). Data on ethanol are also included. For ease of comparison all exposure numbers have been converted to percentage gas volume.

Other FICs (e.g., 1-C₃F₇I, 1-C₄F₉I, 1-C₆F₁₃I) will have different toxicity characteristics from CF₃I and should be thoroughly investigated because of their promise as high-performance solvents and foam blowing agents, both alone and in blends. An important part of the Phase II study is an in-depth investigation of the toxicology of these three compounds.

5. Cleaning Ability

A. Introduction

Cleaning performance is an important factor in the attractiveness of any solvent. Cleaning ability tests were conducted to compare the effectiveness of FICs to that of conventional chlorinated solvents in removing difficult soils commonly encountered in USAF operations. Tests were conducted following standard protocols developed at Sandia National Laboratories and elsewhere. These tests involve preparation of coupons contaminated with simulated soils, cleaning under controlled conditions, and reweighing.

The three highest-ranking pure FIC solvents selected were tested for cleaning effectiveness using coupons contaminated with simulated soils such as hydraulic fluids, oils, greases, solder flux residue, lanolin, wax, and other appropriate contaminants. Each contaminated coupon will be suspended in a beaker of the test solvent with magnetic stirring at room temperature for a set time. The soil remaining was determined by weighing on an analytical balance.

B. Solvents Tested

The FIC solvents tested were pure 1-C₃F₇I, 1-C₄F₉I, and 1-C₆F₁₃I. For comparison, baseline tests with TCA, CFC-113, and TCE were also run for all soils tested.

C. Soils Tested

To aid determination of soils to be used for testing, a survey was taken to determine the range of soils encountered on mechanical equipment for Air Force systems and ground support equipment. This included literature surveys and interviews with personnel responsible for equipment maintenance. Some common contaminants found on metal surfaces in USAF operations are shown in Table 5.

Table 4. Comparison of Toxicity Data on FICs and Other Chemicals in Wide Use

Table 5. Some Common Contaminants found on Metal Surfaces in U. S. Air Force Applications

adhesive from aluminum oxide paper
aqueous film-forming foam (AFFF)
core-cutting lubricants
duct & masking tape residue
fingerprints
fluorinated greases
forming oil such as Houghton-Draw 7007
grease pencil
hydraulic fluids such as MIL-H-5606 and 7808
JP-4
JP-5
JP-8
lanolin
lithium-based lubricants
machining oil from electric discharge machining (EDM)
marker pen
mill markings
molybdenum-based lubricants
oil from compressors
particulates in wide size range (shop and road dust)
polysulfide sealant
preservative oil VV-L-800
salts from alkaline cleaners and seawater
silicone
starch from gloves
tube bending oil
waxes

These contaminants can be grouped into the chemical categories of ionic, nonpolar organic, polar organic, and particulate, all of which exhibit different solubilities. Results of contamination can include corrosion, bond failure, mold growth (tropicalisation), hygroscopy, fracture/dusting, and (for electronics) leakage currents, dendritic growth, capacitance effects, and electrical failure.

The soils listed in Table 6 were selected for testing because they represent a wide range of difficult soils. These soils (containing oils, greases, and particulates) are difficult to remove with conventional solvents because of their low solubility and adhesion to metal surfaces.

The "supersoil" was a combination of marker pen, salt, EDM oil, hydraulic fluid MIL-H-82382, shop dust, and aluminum oxide powder. This supersoil, designed with input from shop personnel at McClellan AFB, was designed to represent realistic soils encountered during repairs of aircraft parts at an air logistics center.

D. Procedure

Cleaning abilities were tested on the 19 difficult soils listed in Table 6, following protocols developed at Sandia National Labs (Ref. 24). For each test a set of four 1" by 3" aluminum coupons were weighed to the nearest 0.01 mg on an analytical balance, soiled on the lower 1/3 of one face, reweighed, then immersed in a magnetically stirred solvent bath consisting of 60 mL of solvent in a 100-mL Pyrex beaker. The soiled faces of the coupons faced inward and glass spacers (stir bars) were used to keep the coupons from touching each other. Coupons were removed after 0.5, 1.0, 2.0, and 5.0 minutes, dried, reweighed, and examined. The percentage of soil removal was plotted versus time. For baseline comparison, all cleaning tests were also conducted using TCA, CFC-113, and TCE.

For soiling samples with supersoil, the following procedure was followed (all soiling refers to only the lower 1/3 of the coupon): (1) one face of the coupon was marked with an X with marker pen, (2) the coupon was dipped into a 5% solution of salt in water and oven-dried at 250°F for 15 minutes, (3) the coupon was dipped into a vigorously agitated supersoil solution (consisting of 1% by volume EDM oil, 1% by volume hydraulic fluid MIL-H-82382, 0.5% by weight shop dust, and 0.25% by weight aluminum oxide powder in hexanes) and oven-dried.

E. Results

The results of these tests are summarized in Table 7 with one-word descriptions of the cleaning abilities of each solvent on each soil tested. The definitions of the terms "excellent" etc. used in Table 7 are given in Table 8. Detailed experimental data are given in Appendix A and graphs of soil removal are given in Appendix B. The conventional chlorinated solvents TCA, TCE, and CFC-113 differ somewhat in their abilities to remove soils; these differences are summarized in Table 7.

These data and graphs show that FICs are excellent solvents, quite similar to TCA, CFC-113, and TCE in cleaning ability for most soils, including AFFF, EDM oil, hydraulic fluids, jet fuels, motor oil, WD40 oil, silicone sealant, silicone spray, and supersoil. FICs are superior to the conventional chlorinated solvents in removal of perfluorinated greases, and are inferior in

Table 6. List of 19 Soils Used for Cleaning Ability Testing

Soil Type	Description
AFFF	from 3M Corp.
beeswax	
castor oil	USP grade from Walgreens, lot 4C9258
EDM oil	Eloxol 76 mfg. by Elox Corp., from Page Products Co., 625 Wanda, Ferndale, MI 45220

removal of beeswax, grease pencil, lanolin, and molybdenum spray lubricant. A chart of removal of perfluorinated grease is shown in Figure 1.

FICs are virtually identical to the chlorinated solvents in removal of supersoil (from which all solvents were effective at removing the EDM oil and hydraulic fluid, but ineffective on salt). All solvents gave similar results with AFFF, removing the organic components but not the small amount of water contained in AFFF, which evaporated after the cleaning. The most difficult soils to remove of the 19 tested were beeswax, castor oil, grease pencil, lanolin, molybdenum grease, molybdenum spray lubricant, and silicone sealant. It should be noted that even if a solvent performed poorly in removing a particular soil in this test, it is expected that in most cases satisfactory removal could be obtained by using some combination of longer soaking times, ultrasonic agitation, and physical methods such as wiping or brushing.

6. THERMAL STABILITY TESTS

A. Introduction

In addition to cleaning ability testing, the other main thrust of Phase I was to examine the thermal stabilities of FICs with and without added stabilizers. The thermal stability of a solvent determines its storage conditions and shelf life. It also has a major bearing on whether the solvent can be used in a constantly-boiling vapor degreaser or can only be used at room temperature. Stabilizers are often used with haloalkane solvents to improve thermal stability and increase storage lifetime. Liquid stabilizers used with haloalkane solvents have been reviewed (Ref. 28). The purpose of the thermal stability testing was to determine the rates of decomposition of 1-C₃F₇I, 1-C₄F₉I, and 1-C₆F₁₃I with and without various potential stabilizers at temperatures from 90° to 175°C. The candidate stabilizers tested were in two classes: solids and liquids. Solids tested included copper metal, silver metal, activated charcoal, molecular sieve (zeolite), and refrigerant filter-drier beads (silica). Liquids tested were combinations of methanol, nitromethane, 1,2-butylene oxide, 1,4-dioxane, 1,3-dioxolan, and furan known to stabilize chlorinated solvents (Ref. 28). Table 9 lists the candidate stabilizers tested.

When FICs decompose, they form molecular iodine (I₂) and the perfluorocarbon corresponding to coupling of two of the perfluoroalkyl radicals. This reaction is shown in Reaction [1].

Molecular iodine is brown, red, or purple depending on the solvent, and absorbs visible light near 540 nm. Iodine dissolved in FICs is pink to purple and absorbs visible light near 510 nm. Known concentrations of iodine in FICs were prepared and their spectra taken to yield a Beer's Law plot of iodine concentration versus absorbance. These plots were used to correlate readings of absorbance to iodine concentration in the aging samples.

a. Solid additives are reported in weight percent; liquids by volume percent.

b. Solid.

According to the Corning Co., the allowable internal pressure in undamaged Pyrex tubing is given in psi by Equation (1)¹.

$$P = 2000W/D \quad (1)$$

where P is the allowable internal pressure in psi, W is the minimum wall thickness in mm, and D is the maximum outside diameter in mm. Placing the values of 2 mm wall thickness and 6 mm outer diameter into this equation yields an allowable internal pressure of 667 psi or 45 atm. Imperfections in the seals will make the tubes able to withstand only lower pressures.

In order to estimate the pressures of the FICs at 175°C, a correlation was made between normal boiling points and vapor pressures at 175°C for several halocarbons and hydrocarbons. The data used are shown in Table 10, and a plot of the data appears in Figure 2 (Ref. 29).

The data shown in Table 10 and Figure 2 gave Equation (2), relating vapor pressure at 175°C (P_{175}) in atmospheres to normal boiling point (B) in °C.

$$P_{175} = 0.0023B^2 - 0.6084B + 44.23 \quad (2)$$

Using Equation (2) to predict the vapor pressures of the three FICs at 175°C gives the results shown in Table 11.

Table 10. Boiling Points and Vapor Pressures at 175°C for Selected Compounds

Compound	BP (°C)	VP at 175°C (atm)
trichlorofluoromethane	23.7	30
diethyl ether	34.6	28
1,1,2-trichloro-1,2,2-trifluoroethane	47.6	20
1,1-dichloroethane	57.3	16
1,2-dichloroethane	83.7	9
toluene	111	5
octane	125.6	3.5
1,2-dibromoethane	131.5	3.5
ethylbenzene	136.2	3

Table 11. Estimated Vapor Pressures of FICs at 175°C

FIC	BP (°C)	Estd. Vapor Pressure at 175°C (atm)
1-C ₃ F ₇ I	40	24
1-C ₄ F ₉ I	67	14
1-C ₆ F ₁₃ I	117	5

¹ For the convenience of the reader, equations are numbered in parentheses and reaction numbers in square brackets throughout this report.

FIGURE 2. VAPOR PRESSURE AT 175°C VS. NORMAL BOILING POINT FOR SELECTED LIQUIDS

Almost none of the tubes containing 1-C₃F₇I survived exposure to 175°C; most exploded within one hour of commencement of heating. However, virtually all the tubes containing 1-C₃F₇I survived prolonged exposure to 150°C, and almost all the tubes containing 1-C₄F₉I and 1-C₆F₁₃I survived prolonged heating at 175°C. Thus the upper limit for integrity of most tubes lay at estimated internal pressures between 14 and 24 atmospheres.

B. Procedures

i. Safety Considerations

FICs are nonflammable and appear from the limited evidence available to have low toxicity. However, as in the case of all research chemicals whose properties are not completely known, standard precautions were taken. All filling was done in a fume hood by a trained chemist wearing goggles and gloves. Exposure was avoided, fumes were not breathed, and skin was rinsed promptly if any contact occurred. Caution was used to avoid touching hot glass or sharp glass fragments.

ii. Calibration of Visible Spectrometry

In order to correlate absorbance of visible light with concentration of iodine, a series of known concentrations of iodine in the FIC solvents was prepared. Before this calibration curve was prepared, spectra of iodine in the three FICs were taken to determine the wavelengths of maximum absorbance of iodine in solution. These wavelengths are listed in Table 12.

Table 12. Wavelengths of Maximum Absorbances of Iodine in FIC Solutions

FIC	Wavelength (nm)
1-C ₃ F ₇ I	506
1-C ₄ F ₉ I	513
1-C ₆ F ₁₃ I	513

Examples of visible spectra showing absorbance maxima for iodine dissolved in FICs are shown in Figures 3 to 5. Figure 3 is a broad-range scan of iodine in 1-C₆F₁₃I from 365 to 700 nm, showing the iodine peak at 450-580 nm. Figure 4 is a shorter-range scan of the same solution from 450 to 550 nm showing the iodine absorbance maximum at 513 nm. Figure 5 is a short-range scan from 420 to 700 nm of iodine in 1-C₃F₇I showing the absorbance maximum at 506 nm.

According to Beer's Law (Equation 3) absorbance (A) is directly proportional to concentration (c), with the constant of proportionality being the absorptivity (ε) times the pathlength through the sample (l).

$$A = \epsilon cl \quad (3)$$

Data to calibrate iodine concentration vs. absorbance were obtained for all three FICs. The data obtained are shown in Table 13. High-quality Beer's Law plots were obtained for all three FIC solvents tested; these are shown in Figures 6 through 8.

FIGURE 6. IODINE CONCENTRATION VS. ABSORBANCE FOR 1-C₃F₇I AT 506 NM

FIGURE 7. IODINE CONCENTRATION VS. ABSORBANCE FOR 1-C₄F₉I AT 513 NM

FIGURE 8. IODINE CONCENTRATION VS. ABSORBANCE FOR 1-C₆F₁₃I AT 513 NM

The equations describing the lines obtained for concentration vs. absorbance for the three FICs are given in Equations (4) through (6).

$$C_3 = -0.0086 + 1.752A \quad (R = 0.999 \text{ for 5 points}) \quad (4)$$

$$C_4 = 0.0107 + 2.495A \quad (R = 0.995 \text{ for 9 points}) \quad (5)$$

$$C_6 = 0.0121 + 0.798A \quad (R = 0.983 \text{ for 9 points}) \quad (6)$$

where A is the absorbance, C is the concentration in mg/mL of iodine in the three, four, or six-carbon FIC, and R is the correlation coefficient.

To convert mg iodine per mL to percent decomposition, the following reasoning can be followed. One mL of C_3F_7I weighs 2.06g and contains $(2.06g)/(295.93g/mole) = 6.96 \text{ mmol}$ solvent. One milligram of iodine corresponds to $(0.001g)/(253.8g/mole)$ or 0.00394 mmol I_2 , which corresponds to 0.00788 mmol atomic iodine. Because each molecule of the FIC decomposing supplies one atom of iodine, this means that 0.00788 mmol of the FIC have decomposed, so the percent decomposition is $(0.00788/6.96) \times 100\% = 0.113\%$. The relationship of percentage decomposition of 1- C_3F_7I to iodine concentration can be summarized by Equation (7).

$$D_3 = 0.113C_3 \quad (7)$$

Similar calculations for the four- and six-carbon FICs yield Equations (8) and (9).

$$D_4 = 0.136C_4 \quad (8)$$

$$D_6 = 0.171C_6 \quad (9)$$

Substituting Equations (4) through (6) into Equations (7) through (9) gives Equations (10) through (12).

$$D_3 = -.0010 + 0.1980A \quad (10)$$

$$D_4 = 0.0015 + 0.3393A \quad (11)$$

$$D_6 = 0.0021 + 0.1365A \quad (12)$$

Equation (10) to (12) were used to convert absorbance data collected to percentage decomposition in the aging samples. These values of absorbance and percentage decomposition are tabulated in Appendices C, D, and E for 1- C_3F_7I , 1- C_4F_9I , and 1- $C_6F_{13}I$, respectively.

iii. Preparation and Labeling of Tubes

Special-walled Pyrex glass tubing (6 mm outer diameter, 2 mm glass thickness) was cut into 8-inch sections and sealed at one end by a professional glassblower. On each tube a constriction was made about one inch from the open end to facilitate later sealing, and the tubes were annealed. Tubes were oven-dried for at least 1 hour at 120°C to remove any traces of moisture. They were removed from the oven, placed in a desiccator, and allowed to cool to room temperature.

In general (with some exceptions) tubes were filled in sets of. Each tube was labeled with a first digit indicating the FIC. This digit was 3, 4, or 6, corresponding to the number of carbons in the FIC. Next came a 3-character description of the additive. Next was a 3-digit number representing the exposure temperature. It should be noted that originally it was planned to expose the tubes to 82, 115, 150, and 175°C and they were labeled as such. Before aging was begun it was decided to raise the two lower temperatures to 90 and 120°C respectively. Therefore all tubes labeled 082 were exposed to 90° and all labeled 115 were exposed to 120°C. The last character in the label was an A, B, C, or D indicating which of the two to four duplicate samples it was. For example, the eight tubes containing the 3-carbon FIC with no additive (NON) were labeled:

3NON082A
3NON082B
3NON115A
3NON115B
3NON150A
3NON150B
3NON175A
3NON175B

Labels were written with permanent aluminum fine-tip marker toward the bottom of the tube, so as not to interfere with spectroscopic readings later. Usually the labels remained legible throughout the filling and aging; they were touched up as needed.

iv. Filling

Pyrex special-walled tubes (6 mm o.d., 2 mm wall thickness) that had been sealed at one end and had a constriction about one inch from the open end were oven-dried, filled with the FIC (about 1.2 mL; the volume did not have to be exact) and appropriate additive, degassed with argon or nitrogen, cooled in liquid nitrogen, attached to a manifold, cooled further in liquid nitrogen, evacuated using a vacuum pump, backfilled with nitrogen gas, evacuated again, and sealed under vacuum at the constriction by a glassblower. The tubes were then aged in ovens at 90°, 120°, 150°, and 175°C for up to four months. Further procedural details are provided below. The tubes were removed periodically from the heating ovens, cooled briefly, and analyzed for decomposition by reading the absorbance at 510 nm. This method had the advantage that the same samples could be heated and monitored for decomposition over an extended time.

Caution was used in carrying the tubes. No more than 3 or 4 tubes were lifted at a time if not in a container, because the middle tubes in a bunch lifted by hand tended to drop out (and break).

v. Aging

Four ovens were maintained at 90°, 120°, 150°, and 175°C ($\pm 3^\circ\text{C}$), respectively. Each oven had a thermocouple connected to a central datalogger that recorded temperature versus time. Each sealed tube was placed inside a section of copper tubing 1/2" diameter by 8" long, open at both ends. This precaution was taken so that if a tube exploded from the internal pressure it would not damage other tubes. Periodically (about once a week) the ovens were shut off to allow the tubes to cool briefly and spectroscopic readings of each tube were recorded.

vi. Analysis

As the tubes were aged, they were removed periodically from the heating ovens, cooled briefly to room temperature, and the absorbance at 510 nm was recorded to indicate the extent of decomposition. For each reading, a reference reading of light counts (in arbitrary units) with no sample present was also taken. The absorbance was calculated using Equation (13).

$$A = \log (\text{reference counts/sample counts}) \quad (13)$$

Changes in absorbance from initial readings were calculated. Percentage decomposition was calculated using Equations (10)-(12) and changes in percent decomposition from initial readings were determined.

Raw hours (total hours since tube was first placed in the oven) were calculated from the dates of readings, then the cumulative times the tubes were out of the ovens (obtained from the datalogger records) were subtracted to give the actual hours of heating.

C. Results

Over 3000 spectroscopic readings were recorded over a period of 120 days. Tabulated data from the aging samples are given for 1-C₃F₇I in Appendix C, 1-C₄F₉I in Appendix D, and 1-C₆F₁₃I in Appendix E. These data tables include tube identification numbers, dates of readings, index numbers (indicating order of readings on a given date), total light counts from the reference beam, light counts through the samples, comments, calculated absorbances, changes in absorbance from initial readings, percentage decomposition, and changes in percentage decomposition from initial readings, raw hours since start of heating, actual hours heated, temperature, and additives present.

Overall aging results are summarized in Table 14. Table 14 shows, for each FIC with each additive at each temperature tested, whether decomposition was zero, slight, or extensive. For those sets of samples that showed slight decomposition, two types of graphs were prepared: percent decomposition vs. time and percent decomposition at final readings vs. temperature of aging. Where judged appropriate, least-squares fitted functions were obtained. The best-fitting function (linear, logarithmic, or second-order polynomial) was used in each case. These graphs are included in Appendix F. The following sets of tubes showed good kinetics (gradation to darker colors at higher temperatures) with slight decomposition: 3AIR, 3A_W, 3FIL, 3NON, 4AIR, 4NON, 4WAT, 6AIR, 6FIL, 6NON, and 6WAT.

Overall, the results indicated that pure FICs underwent less than 0.6% decomposition at 175°C for 4 months, and that all the solid stabilizers helped prevent even this minimal accumulation of decomposition products. All liquid stabilizers failed, leading to severe decomposition.

All tubes with silver were water-clear, showing that silver was the best stabilizer. For tubes with copper, all were water-clear except 1-C₄F₉I and 1-C₆F₁₃I at 175°C. (The tube with 1-C₃F₇I and copper exploded on heating to 175°C and no data were obtained 1-C₃F₇I at 175°C). These observations showed that copper was an effective stabilizer, but not as effective as silver, and that it reached its limits of effectiveness below 175°C under the test conditions.

There are two possible mechanisms to explain the observation that solid additives led to lower observed amounts of the iodine decomposition product. Either the additive prevents decomposition of the solvent, or the additive is adsorbing iodine on the surface (and possibly reacting with iodine). At this time, with the data now available, it is not possible to determine which mechanism is operating. Further studies, such as gas chromatographic (GC) analysis, would clarify the situation. Such studies are planned as part of Phase II of this effort.

Results of the tests for effects of light are summarized in Table 15. For all FICs, less than 0.07% decomposition was observed in bright sunlight for 350 hours exposure (corresponding to 700 hours of outside exposure). These results show that exposure to room light and moderate amounts of sunlight are not of concern. It should be kept in mind that the Pyrex tubes absorb wavelengths shorter than visible light and would serve to protect the FICs to some degree from the full effects of sunlight. However, it has been shown that even visible light possesses sufficient energy to break the C-I bonds in FICs (Refs. 9 and 12). The fact that more extensive decomposition was not observed on exposure of FICs to bright sunlight at an elevation of 5000 feet in summertime is encouraging in that it indicates FICs are not highly susceptible to photolysis during use.

To examine the relative stabilities of the three FICs tested, data for all three FICs under comparable conditions were collected in Table 16. These conditions were selected because data were available on all three FICs, and slight decomposition was observed. Comparisons of the three FICs could not be made effectively in cases where no decomposition or extensive decomposition occurred. If no decomposition was observed, then the FICs appeared equal in stability. If extensive decomposition was observed, accurate readings of absorbance could not be obtained.

The data in Tables 15 and 16 show no definite trends of stability in the series of FICs. One subjective observation made was that 1-C₆F₁₃I tends to take on a purplish tinge on storage much more quickly than either of the other two FICs. Thus there may be a slight tendency to decreased thermal stability with increasing chain length of the FIC, although no numerical evidence for this trend was observed.

No evidence of decomposition was observed for 1-C₃F₇I in the presence of copper, silver, molecular sieve, or filter-drier beads up to 150° (the maximum temperature tested). Only slight decomposition was observed at 150° for no additive (0.09% at 120 days) or air (0.29% at 100 days). Exposure to darkness or room light at room temperature gave no detectable decomposition.

Table 14. Summary of Extent of Decomposition Observed for Different Additives and Conditions

(Key: d = decomposition extensive, n = no decomposition, s = slight decomposition)

Additive	90°			120°			150°			175°

Table 15. Summary of Extent of Decomposition of FICs Under Different Lighting Conditions

(Key: N = no decomposition, S = slight decomposition)

Light Conditions	1-C ₃ F ₇ I	1-C ₄ F ₉ I	1-C ₆ F ₁₃ I
DARK (DRK)	N	N	N
ROOMLIGHT (RML)	N	N	S
SUNLIGHT (SUN)	S	S	S

Table 16. Percentage Decomposition Observed for Different FICs Under Comparable Conditions

FIC	Sunlight, 700 hrs	FIL 175°C, 120 days	NON 150°C, 120 days	AIR 150°C, 120 days
1-C ₃ F ₇ I	0.069	0	0.082	0.282
1-C ₄ F ₉ I	0.053	0.218	0.317	0.451
1-C ₆ F ₁₃ I	0.046	0.222	0.177	0.192

No evidence of decomposition was observed for 1-C₄F₉I up to and including 175°C in the presence of silver. With copper and filter-drier beads, 1-C₄F₉I showed no decomposition through 150°C and slight decomposition at 175°C (0.44% for copper, 0.22% for filter-drier beads). Perfluorobutyl iodide with no additive or water showed no decomposition through 120°C and slight decomposition at 150°C and 175°C (0.32% for no additive, 0.44% for water at 150°C). Exposure to darkness or room light at room temperature gave no detectable decomposition.

For 1-C₆F₁₃I, no evidence of decomposition was observed up to and including 175°C in the presence of silver. Copper and filter-drier beads gave protection through 150°C. Exposure to darkness at room temperature gave no detectable decomposition; exposure to room light or sunlight gave traces of decomposition products.

For all three FICs, comparison of graphs of percent decomposition vs. time for the pure FICs and for air and water added shows that neither air nor water had any detectable effect on the rate or extent of decomposition.

The best stabilizer was silver metal, which protected all three FICs from decomposition at 175°C for more than 120 days (the length of this test). Copper and molecular sieve protected all three FICs up to 150°C for 120 days, but showed slight traces of decomposition products at 175°C. Charcoal and filter-drier beads gave some protection against decomposition compared to no additive, but less protection than silver, copper, or molecular sieve.

7. Materials Compatibility

A. Introduction

Solvents must not damage the materials they contact. Although no materials compatibility tests were proposed or funded in Phase I, because of the importance of this information some preliminary tests were carried out during the course of the Phase I studies. The materials compatibility tests were above and beyond the required tasks and were performed at no cost to the Government.

B. Polymers Tested

i. Procedures

Testing was based on the method described in the American Society for Testing and Materials (ASTM) Standard D471-79 (revised 1991) "Rubber Properties-Effects of Liquids," which references ASTM Standards D412 and D751 (Ref. 30). For each polymer tested, three O-rings were labeled by tying zero, one, or two pieces of cotton string around each O-ring for samples number one, two, and three, respectively. Each O-ring was weighed and the cross-sections (in four readings 90° apart) and inner diameter across the O-ring (in two readings 90° apart) were measured with digital calipers and recorded. Each set of three O-rings was placed into a 4-oz brown bottle with 15 mL of the appropriate FIC (1-C₃F₇I, 1-C₄F₉I, or 1-C₆F₁₃I). The bottles were capped and stored in the dark at room temperature. The samples were observed periodically for two weeks, then the O-rings were removed, allowed to dry at room temperature for about an hour, and weight and dimensions were remeasured.

ii. Results

A material failed if any of the following occurred: (1) any dimension changed by 10% or more, (2) the weight changed by 20% or more, or (3) the material became hard or brittle or showed other obvious degradation. The experimental data on polymer compatibility tests of FICs are given in Table 17. The results showed that 1-C₃F₇I, 1-C₄F₉I and 1-C₆F₁₃I are compatible with Viton, Neoprene, ethylene propylene rubber (EPR), fluorosilicone, butyl rubber, and Teflon. These FICs are incompatible with Buna-N (nitrile), silicone rubber, and polyurethane O-rings on prolonged immersion. A summary of compatibilities of FICs and a comparison with compatibilities of other halogenated compounds is given in Table 18 (Refs. 31 and 32). Table 18 shows that the range of compatibilities of FICs is quite similar to the ranges of other halogenated hydrocarbons. There should be no significant difficulties finding polymers to use in prolonged contact with FICs. For brief contact (e.g., washing of a part containing a polymer) there should be no problem even for those polymers that are incompatible on prolonged immersion.

Table 17. Experimental Data on Compatibility of Polymers with FICs

Polymer Type	FIC	Sample	Cross-section before (mm)	Avg.	Cross-section after (mm)	Avg.	Diff. % ID Before (mm)	Avg.	ID after (mm)	Avg.	Diff %	Int. Wt. (g)	Final Wt (g)	Diff %	Comments	Pass or Fail

silicone		N	N	U	N	U	U	N	N	N
styrene-butadiene rubber (SBR)		N	Y	Y	Y	Y	Y	U	N	U

C. Metals Tested

i. Procedures

Compatibility testing with metals was also carried out based on ASTM method D2251, "Standard Test Method for Metal Corrosion by Halogenated Organic Solvents and Their Admixtures" (Ref. 33). Preliminary compatibility testing of FIC solvents was carried out with the metals shown in Table 19.

Table 19. Metals Used for Compatibility Testing with FICs

Metal	Abbreviation Used
Aluminum 2024	Al2
Aluminum 5052	Al5
Aluminum 6061	Al6
Aluminum 7075T6	Al7
Brass	Bras
Bronze	Bron
Cast iron	Fe
Copper	Cu
Magnesium	Mg
Mild steel	MS
Stainless steel 303	SS3
Stainless steel 416	SS4
Titanium	Ti

To conduct the tests, three coupons of each metal were prepared and engraved with identifying numbers (e.g., Al7-3) in which the final number indicated the carbon number of the FIC tested (1-C₃F₇I, 1-C₄F₉I, or 1-C₆F₁₃I). The coupons were placed in Pyrex test tubes with threaded closures and 5 mL of the appropriate FIC was added to each. The tubes were sealed, kept in the dark at room temperature, and examined periodically. Total exposure time was 90 days; this exposure time was much longer (and therefore more severe) than the standard 10-day test.

ii. Results

The results of the metal compatibility tests are given in Table 20. Table 20 lists initial weights, final weights, and observations. All of these metals, with the exception of mild steel, showed excellent compatibility with all three FICs tested. The mild steel showed significant oxidation, but that could well be due to air and moisture which were not rigorously excluded. More detailed investigation of the effects of FICs on mild steel will be conducted in the Phase II effort.

Table 20. Experimental Data on Compatibility of Metals with FICs

Metal	Sample No.	Init. wt. (g)	Final wt. (g)	Wt. Change (g)	% Wt. Change	Observations
Aluminum 2024	Al2-3	2.70645	2.70661	0.00016	0.01%	No visible changes.
	Al2-4	2.68693	2.68806	0.00113	0.04%	No visible changes.
	Al2-6	2.71631	2.71701	0.00070	0.03%	Barely noticeable discoloration on submerged part.
Aluminum 5052	Al5-3	2.52445	2.52467	0.00022	0.01%	Almost no visible changes. Bare visible white residue on small part of surface just above liquid level.
	Al5-4	2.56312	2.56388	0.00076	0.03%	Small amount white material on surface directly above liquid line and very bottom.
	Al5-6	2.54014	2.54205	0.00191	0.08%	Tiny amount white oxidation on submerged surface.

8. Conclusions

In Phase I, the known properties of pure FICs and potential blending agents were tabulated and laboratory testing was carried out to determine thermal stability and cleaning effectiveness of pure FIC solvents. The results of the Phase I effort have shown that all three FICs tested (1-C₃F₇I, 1-C₄F₉I, and 1-C₆F₁₃I) have high cleaning effectiveness on a wide variety of difficult soils, excellent thermal stability, and excellent materials compatibility. The *most* attractive as a general replacement for TCA and CFC-113 appears to be 1-C₄F₉I, because of its physical properties (e.g., boiling point and vapor pressure between those of TCA and CFC-113) and high cleaning performance.

Phase I of this effort has demonstrated the feasibility of the approach taken to finding environmentally compliant solvents, and has provided a list of top-ranking nonflammable, nonaqueous, non-ozone-depleting FIC solvents. It has shown that pure FICs undergo less than 0.6% decomposition when exposed to 175°C for four months, and that several solid stabilizers are effective in preventing the accumulation of even these small amounts of decomposition products. It has been shown that neither air nor water affect the stabilities of FICs.

The results have demonstrated the technical feasibility of fluoroiodocarbons solvents as "drop-in" replacements for CFC-113, TCA, TCE, and PCE. Phase I has validated all three FICs tested as high-performance, nonflammable, nonaqueous, non-ozone-depleting FIC solvents for further Phase II development.

The solvents developed in this effort are expected to find wide application not only in cleaning of metals but also of electronics and precision surfaces. This technology is ideally suited for dual use: both military and civilian sectors rely heavily on solvent cleaning. FICs are expected to provide superior cleaning at lower cost than CFCs and other alternatives. They will replace ozone-depleting substances with environmentally safe solvents. They may allow continued use of vapor degreasers without disruption of established manufacturing procedures. These solvents could save hundreds of millions of dollars by allowing continued use of existing vapor degreasers. In addition, this effort will assist development of related FIC-containing blends that show promise as effective and environmentally safe refrigerants, foam blowing agents, and firefighting agents.

Once the best solvents have been identified and validated, a new industry in FIC-containing solvents will be created that will create many new jobs for Americans in several areas of chemical manufacturing, cleaning, and recycling. Many technically trained individuals are already well qualified for these jobs and would not require substantial retraining.

9. Transitional Tasks Underway

The transitional phase now in progress between Phase I and Phase II will model the properties of blends of conventional solvents with FICs and identify top-ranking blends for Phase II testing.

In the optional transitional effort now underway, two objectives will be met:

(1) *Identification of azeotropic and near-azeotropic solvent blends containing FICs.*

Azeotropes are mixtures of two or more chemicals that do not separate on evaporation. In terms of physical properties, the mixture behaves much like a single chemical. An azeotropic

mixture has several logistical advantages over simple blends. The properties of an azeotrope are highly predictable. Since the composition does not change on evaporation, a partially empty system can be safely topped up without chemical analysis. Recovery and recycling are made much easier. Potential concerns about FICs, including cost and toxicity, can be reduced by using blends.

Properties of blends will be calculated using ETEC's proprietary thermodynamic computer program called AZEO, and likely azeotropic blends will be identified. Laboratory testing will then be done in Phase II to confirm or disprove the formation and compositions of these azeotropes and near-azeotropes.

AZEO calculates properties of mixtures and predicts azeotrope formation and composition. Mathematical modeling in this program is based upon the theory of corresponding states using a third order virial equation of state. AZEO uses the well-documented Soave modification of the Redlich-Kwong equation of state. The required inputs for each chemical are the molecular weight, normal boiling point, critical temperature, critical pressure, and Pitzer acentric factor (which can be calculated).

The AZEO program reproduces all known azeotropes tested (such as R-500 and R-502) within 1% accuracy. AZEO runs on a PC, works for up to five-component mixtures, and allows a choice of units. It identifies probable azeotropes, near-azeotropes, and non-azeotropes. For azeotropes and near-azeotropes, it gives the approximate azeotropic composition. It calculates vapor pressure curves and gives enthalpies of vaporization and specific heats of liquid and vapor as functions of temperature. AZEO provides pressure-volume-temperature data with an accuracy within 1% and enthalpies of vaporization within 2%. AZEO is only a tool for initial screening to identify attractive blends and possible azeotropes; results obtained from AZEO will be validated by laboratory measurements.

In this task, AZEO will be used to predict the properties of possible blends consisting of one component from Table 1 and one component from Table 2.

(2) Selection of optimal blends containing FICs

Optimal solvent blends will be selected based on the properties of the pure components and the calculated properties of the blends determined by the AZEO program. Properties to be considered in the ranking include physical properties such as boiling point, vapor pressure, and heat of vaporization as well as toxicity, flammability, materials compatibility, thermal stability, environmental effects, and cleaning effectiveness. Environmental properties considered include atmospheric lifetimes, global warming potentials, recyclability, biodegradability, breakdown products, and contributions to tropospheric air pollution (smog).

The predicted properties of blends based on the information on pure and the calculated properties of blends will be screened to determine optimal solvent blends for Phase II testing. Properties to be considered include physical properties, cleaning effectiveness, toxicity, environmental effects, and cost. Those blends identified by the modeling as showing the likelihood of azeotropic or near-azeotropic behavior will be particularly attractive and will be identified for laboratory investigation in Phase II. Special emphasis will be given to blending solvents that have high cleaning effectiveness on the soils for which FICs are less effective: beeswax, castor oil, grease pencil, lanolin, molybdenum grease, molybdenum spray lubricant, and

silicone sealant. Preliminary results from the optional transition tasks indicate that blends of 1-C₄F₉I with isopropyl alcohol or cyclohexane may provide attractive nonflammable azeotropic blends and good solubility properties.

Based on the information collected, approximately 12 of the most promising solvents will be selected for additional laboratory testing. Solvents will be ranked for attractiveness on the basis of probable high cleaning effectiveness, high compatibility with materials, low toxicity, and low environmental impact. Preliminary results from the optional transition tasks indicate that blends of 1-C₄F₉I with isopropyl alcohol or cyclohexane may provide attractive nonflammable azeotropic blends.

10. Planned Phase II Effort

Phase II will further develop and optimize the materials demonstrated in Phase I and will provide in-depth evaluations and larger-scale testing of high-ranking materials identified in Phase I. In Phase II the top-ranking solvents will be tested for formation of azeotropic blends and the properties of these blends as well as the pure FICs will be studied in depth. Flammability, cleaning effectiveness under realistic conditions, materials compatibility, thermal stability, and compatibility with existing cleaning equipment and procedures will be tested. All required toxicity information for regulatory approval under the EPA SNAP program will be obtained and the SNAP applications for the top solvents will be prepared and filed. The methods of synthesis of FICs will be assessed and improved. The Phase II effort will provide all the information needed for regulatory approval and commercial production of FIC-based solvents.

The proposed Phase II effort validates the performance, nonflammability, and low toxicity of pure FICs and blended solvents. The result will be a set of FIC-based solvents validated, approved, and ready for commercial production. Phase II will further develop and optimize the FIC solvents demonstrated in Phase I and will provide in-depth evaluations and larger-scale testing. In Phase II the top-ranking FIC-based solvents will be tested for formation of azeotropic blends, flammability, toxicity, cleaning effectiveness under realistic conditions, materials compatibility, and compatibility with existing cleaning equipment and procedures.

Likely azeotropic nonflammable solvent blends identified in the transitional phase using the AZEO program will be tested in the laboratory. Blends of the components will be made, distilled and the temperature vs. volume of the distillate will be plotted to observe evidence of azeotrope formation. A leveling of the temperature-volume curve below the boiling points of both components indicates a low-boiling azeotrope. A leveling above the boiling points indicates a high-boiling azeotrope. When evidence of azeotrope formation is observed, aliquots (small samples) will be removed and analyzed by gas chromatography to determine the compositions.

In Phase II, the flammability of a range of blends of interest will be determined by testing based on ASTM standard methods. ASTM methods to be used as guides include D92 (*Flash and Fire Points by Cleveland Open Cup*), D1310 (*Flash Point and Fire Point of Liquids by Tag Open-Cup Apparatus*), E502 (*Selection and Use of ASTM Standards for the Determination of Flash Point of Chemicals by Closed Cup Methods*), and E681 (*Limits of Flammability of Chemicals*). Graphs of flammability versus composition will be prepared to determine which blends are flammable, which are combustible, and which are nonflammable.

Cleaning effectiveness will be determined with a variety of soils and substrates under realistic conditions. Test samples will include metal and polymer coupons with simulated soils and printed wiring boards (PWBs) with surface mount technology (SMT) devices. The samples will be cleaned and may be analyzed for contaminants using highly accurate, sophisticated analytical tools such as FTIR reflectance, electron spectroscopy for chemical analysis (ESCA), Auger spectroscopy, and secondary ion mass spectrometry (SIMS), as well as simpler methods such as contact goniometry and surface ionic resistance (SIR).

The compatibility of the solvents will be tested with additional polymers such as polyfunctional FR-4, high-temperature epoxy, bismaleimide triazine epoxy, cyanate esters, and polyimide. Additional studies will be conducted on the compatibilities of FICs with mild steel.

The solvents will be tested in a variety of existing vapor degreasers and other cleaning equipment to see what, if any, modifications are needed. The compatibility of the new solvents with existing vapor degreasers and other existing cleaning equipment will be assessed. If necessary, stabilizers will be added to the solvents. Process performance, hardware costs, materials usage and costs, and hazardous waste generation will be investigated. If incompatibilities are found with existing equipment, the changes needed will be defined.

Flammability testing will be carried out on blends containing varying concentrations of FICs to determine the minimum concentrations needed to make the mixtures nonflammable.

It is anticipated that certain portions of the Phase II efforts may be conducted in collaboration with organizations such as the Air Force Center for Environmental Excellence at Brooks AFB, Texas, the National Defense Center for Environmental Excellence in Johnstown, PA, the Environmentally Conscious Manufacturing (ECM) division of Sandia National Labs in Albuquerque, Lawrence Livermore National Labs in Livermore, California, and/or the National Center For Manufacturing Sciences (NCMS) in Ann Arbor, Michigan. Several of these organizations have been contacted and have expressed interest in testing FIC-based solvents. Possible collaborations have also been discussed with Martin Marietta, Texas Instruments, Hewlett-Packard, Dow Chemical, Branson Electronics, Seagate Technologies, and Motorola. Strategic alliances will be developed to produce and market the top-ranking solvents. It is anticipated that collaboration with such major chemical producers as Du Pont, Dow, or Allied-Signal will be undertaken.

In Phase III, the commercialization of the best solvents validated in Phase II will be carried out. The feasibility of using these solvents will be demonstrated on a pilot manufacturing scale, and agreements for bulk production will be made. Developmental toxicity testing and a worker exposure assessment will be conducted. Developmental toxicity testing involves prolonged (1- to 2-year) exposure of rodents to the test chemical and thorough examination of their offspring for defects. This study costs about \$150-200K and can be carried out by Pharmaco LSR or several other high-quality laboratories. The worker exposure assessment consists of four steps: (1) establishing occupational exposure guidelines, (2) development of an air sampling protocol, (3) measuring exposures in a pilot or larger-scale production facility, and (4) comparing exposures to the occupational exposure limits to establish any necessary engineering controls. Worker exposure assessment can be conducted by Environ, the sister company to Pharmaco LSR; one contact at Environ is Dr. Joe Rodricks (phone 703-516-2345); another is Mark Katchen (phone 714-261-5151).

The Phase III effort will bring to market a new family of nonaqueous solvents with proven cleaning ability, nonflammability, low toxicity, and negligible environmental impact. These solvents are expected to provide the best alternative cleaners for a wide variety of USAF applications.

APPENDIX F:
GRAPHS OF PERCENT DECOMPOSITION
VS. TIME OR TEMPERATURE

Percent Decomposition of 1-C₃F₇I vs. Time at 150°C

Percent Decomposition of 1-C₃F₇I vs. Time at 150°C with Air Added

Percent Decomposition vs. Temperature for 1-C₃F₇I at 120 Days

Percent Decomposition vs. Time for Pure 1-C₄F₉l at 120°C

Percent Decomposition vs. Time for Pure 1-C₄F₉l at 150°C

Percent Decomposition vs. Time for Pure 1-C₄F₉I at 175°C

Percent Decomposition vs. Time for 1-C₄F₉I at 175°C with Air Added

Percent Decomposition vs. Time for 1-C₄F₉l at 175°C with Copper

Percent Decomposition vs. Time for 1-C₄F₉l at 175°C with Filter-drier Beads

Percent Decomposition vs. Time for 1-C₄F₉l at 175°C with Molecular Sieve

Percent Decomposition vs. Time for 1-C₄F₉l at 150°C with Water Added

Percent Decomposition vs. Time for Pure 1-C₆F₁₃l at 120°C

Percent Decomposition vs. Time for Pure 1-C₆F₁₃l at 150°C

Percent Decomposition vs. Time for Pure 1-C₆F₁₃l at 175°C

Percent Decomposition vs. Time for 1-C₆F₁₃l at 150°C With Air Added

Percent Decomposition vs. Temperature for 1-C₆F₁₃l at 175°C With Air Added

Percent Decomposition vs. Time for 1-C₆F₁₃I at 175°C with Copper

Percent Decomposition vs. Time for 1-C₆F₁₃I at 175°C With Filter-Drier Beads

Percent Decomposition vs. Time for 1-C₆F₁₃I at 175°C with Molecular Sieve

Percent Decomposition vs. Time for 1-C₆F₁₃I at 150°C With Water Added

Percent Decomposition vs. Time for 1-C₆F₁₃I at 175°C With Water Added

Percent Decomposition vs. Temperature for Pure 1-C₆F₁₃I at 120 Days

Percent Decomposition vs. Temperature for 1-C₆F₁₃I
with Air at 120 Days

Percent Decomposition vs. Temperature for 1-C₆F₁₃I
with Copper at 120 Days

Percent Decomposition vs. Temperature for 1-C₆F₁₃I
With Filter Drier Beads at 120 Days

Percent Decomposition vs. Temperature for 1-C₈F₁₃I
With Molecular Sieve at 120 Days

Percent Decomposition vs. Temperature for 1-C6F13I
With Water Added at 120 Days
